

Creating cluster in JBoss EAP in domain mode

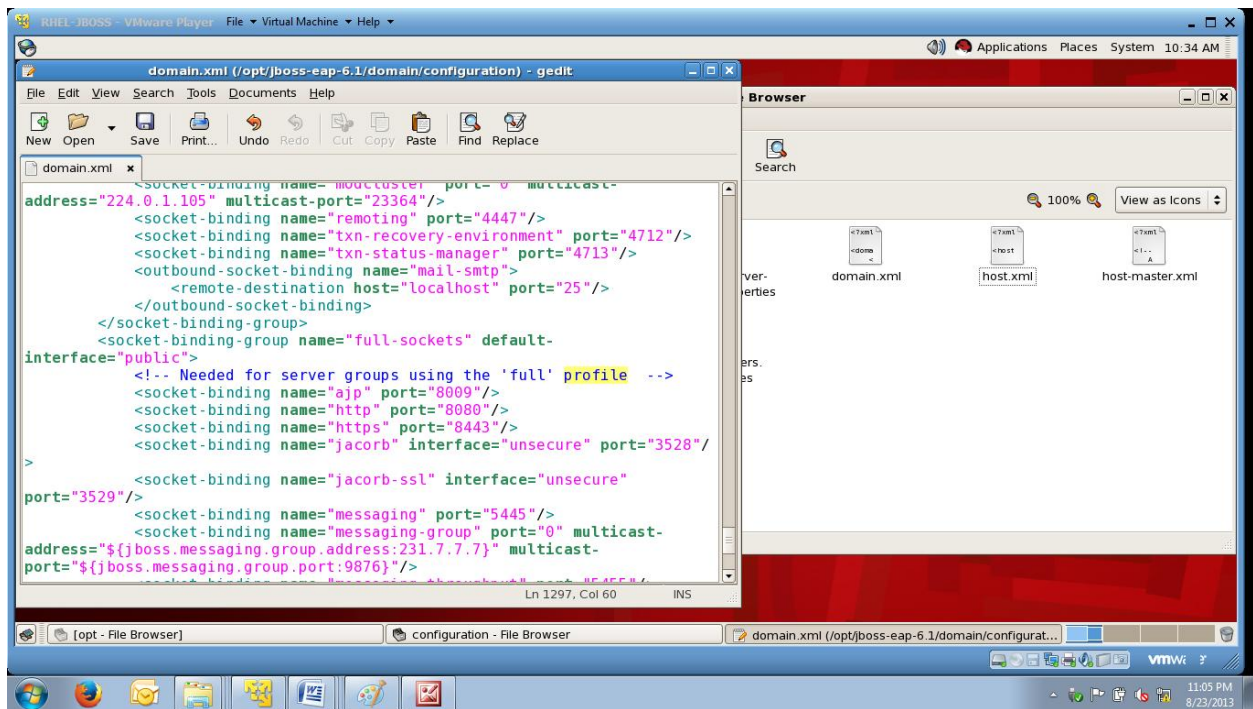

Goto domain/configuration/domain.xml" file make the below changes, which is just adding a new **server-group** (i.e. **ha-server-group**) which would be using **ha** profile and **ha-sockets** socket binding group, **where ha is for cluster enabled**.

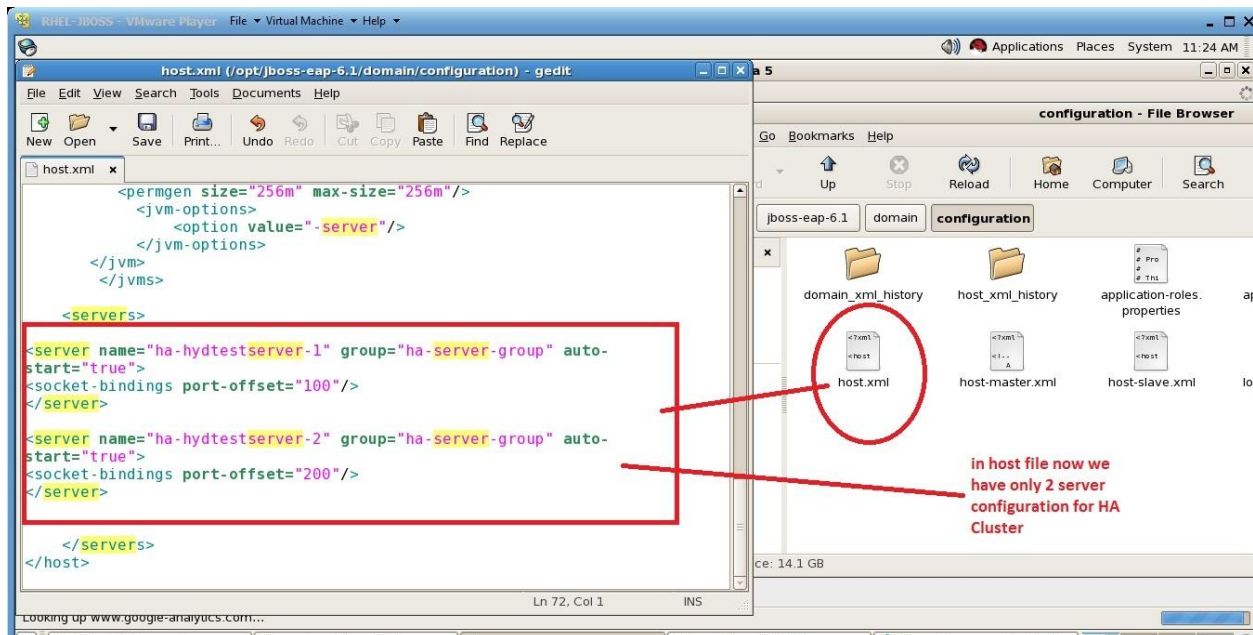

Where:

1. **profile:** tells which type of profile is been used (i.e. web, messaging, cluster, full)
2. **socket-binding-group:** tells which all type of protocols is been used (i.e. web [http,ajp], messaging, jgroups [udp, tcp], full)
3. **server-group :** tells what **profile** is been used and what type of **sockets** is been used

After that you would have to make the below changes in “/opt/jboss-as-6.1.Final/domain/configuration/host.xml” file which is just adding two new JBoss nodes with the name **ha-server-1** and **ha-server-2** which are using the **ha-server-group** server group created in the pervious setp and making **this servers clustered enabled**

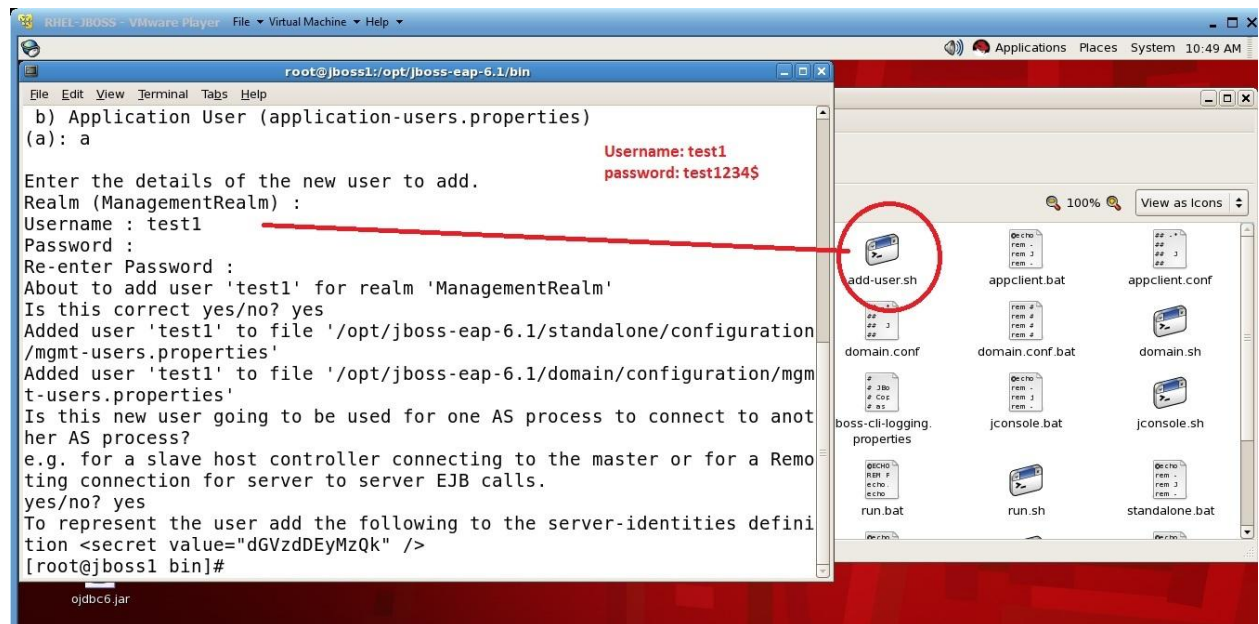

Note: You are giving unique **name** and **port offset** for these servers, as both the servers are running on the same box.

Port offset-----to increase the port nos

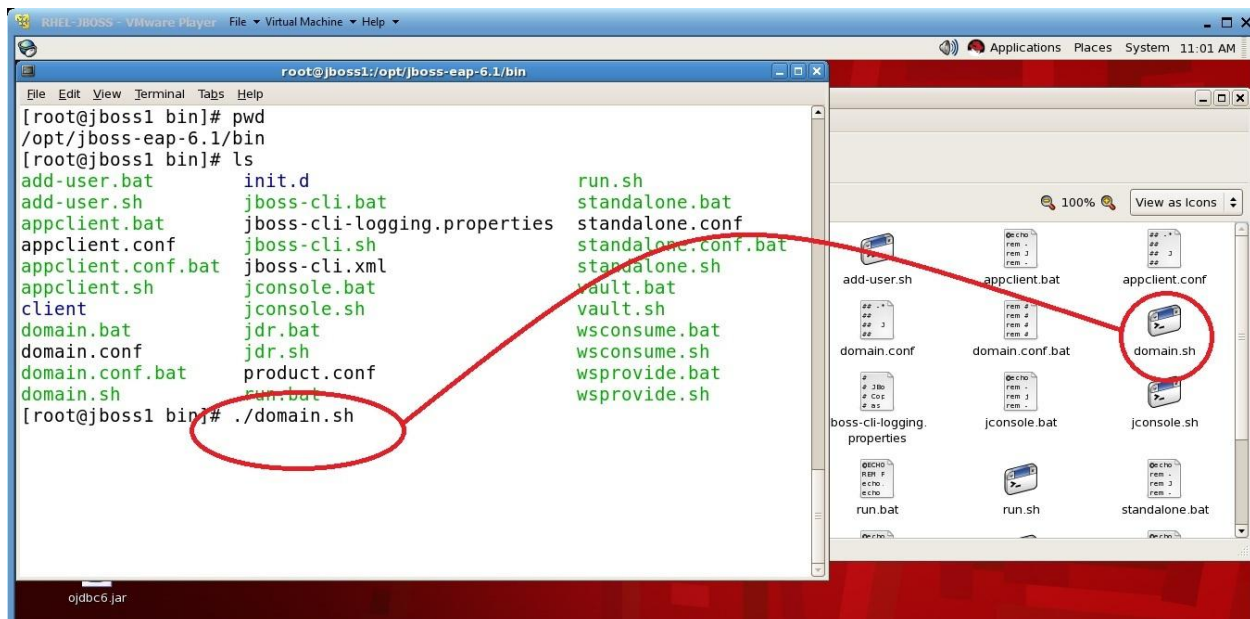

Create a **Management User** using the **add-user.sh** script as shown below. This is done so that we can access admin console.

Username: test1 password: test1234\$

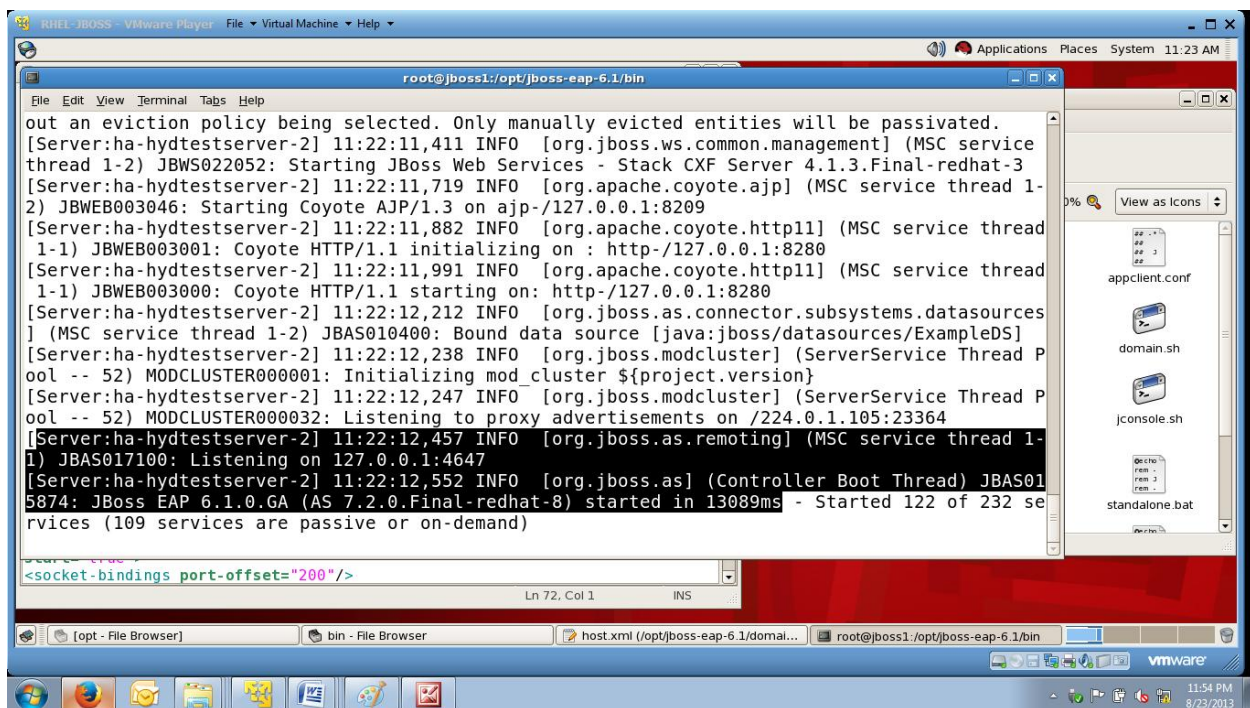

Once everything is done start your server by using the below command, however you would not see that the nodes **ha-server-1** and **ha-server-2** are in a cluster for that you would have to deploy an application which has the **distributable** tag in **web.xml**

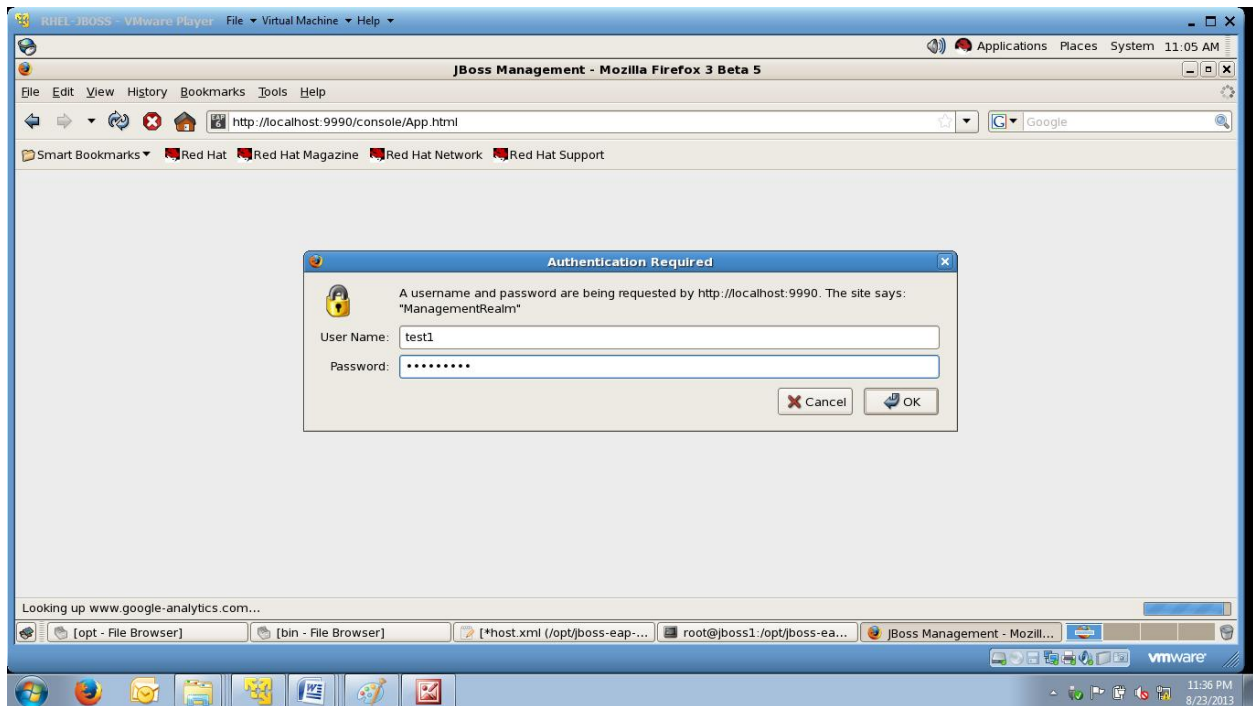

Starting the Server

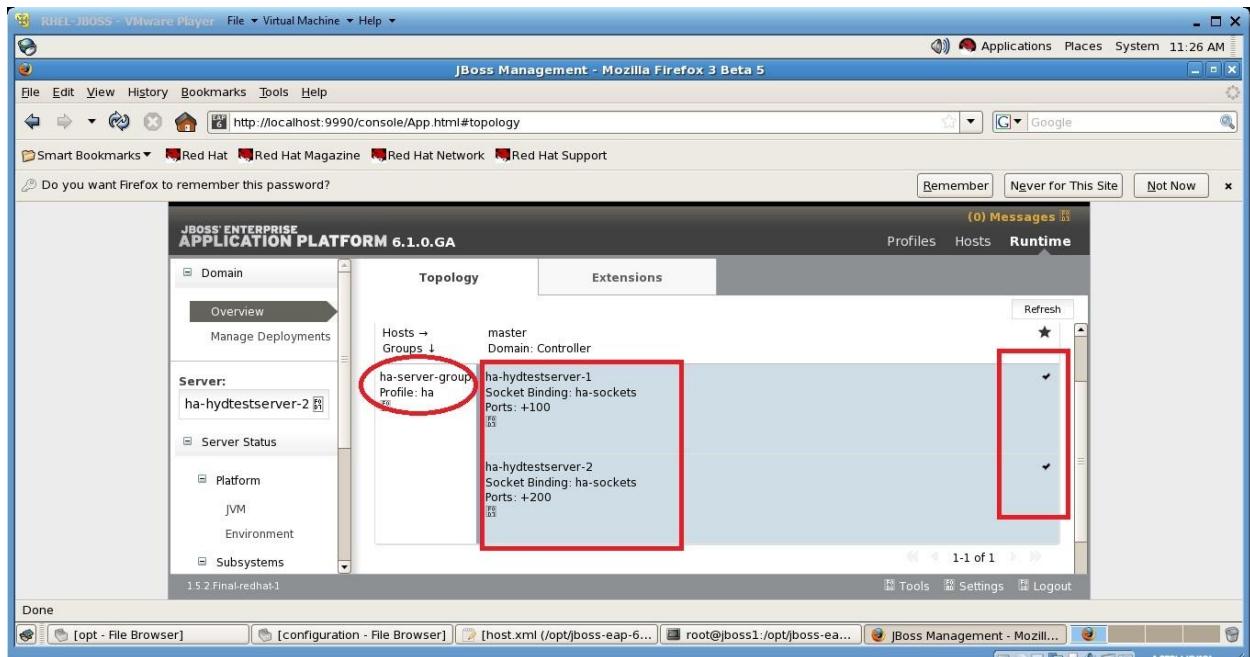

domain.sh -b 192.168.37.150 -Djboss.bind.address.management=192.168.37.150

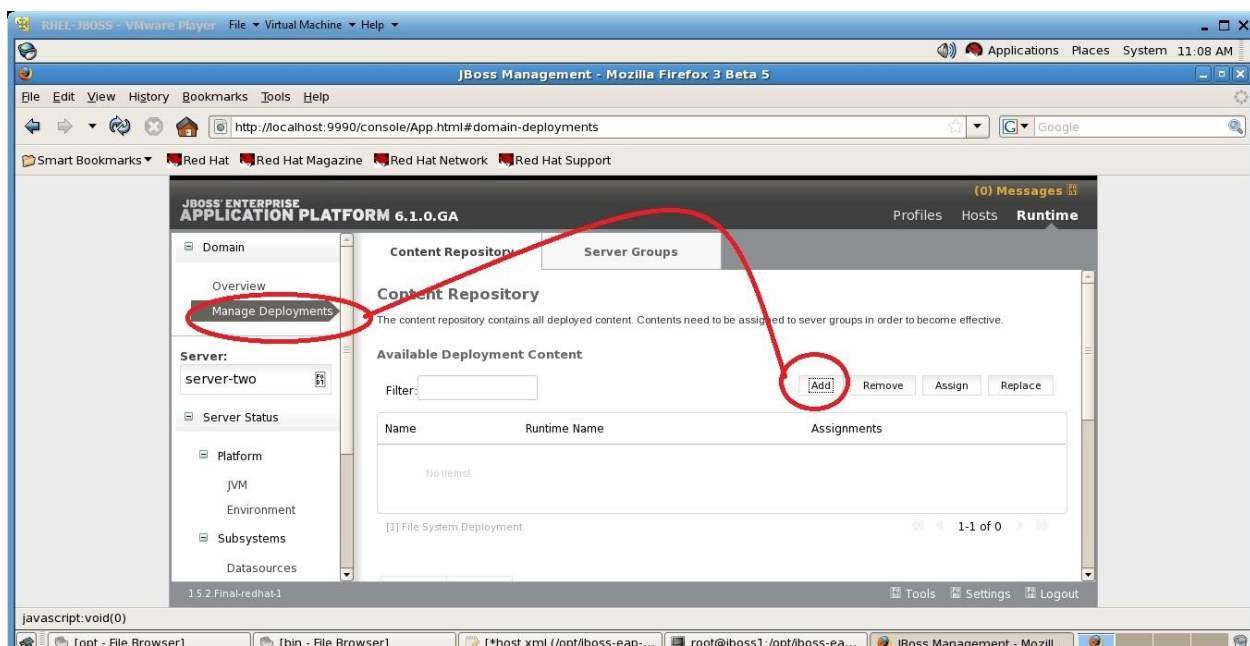

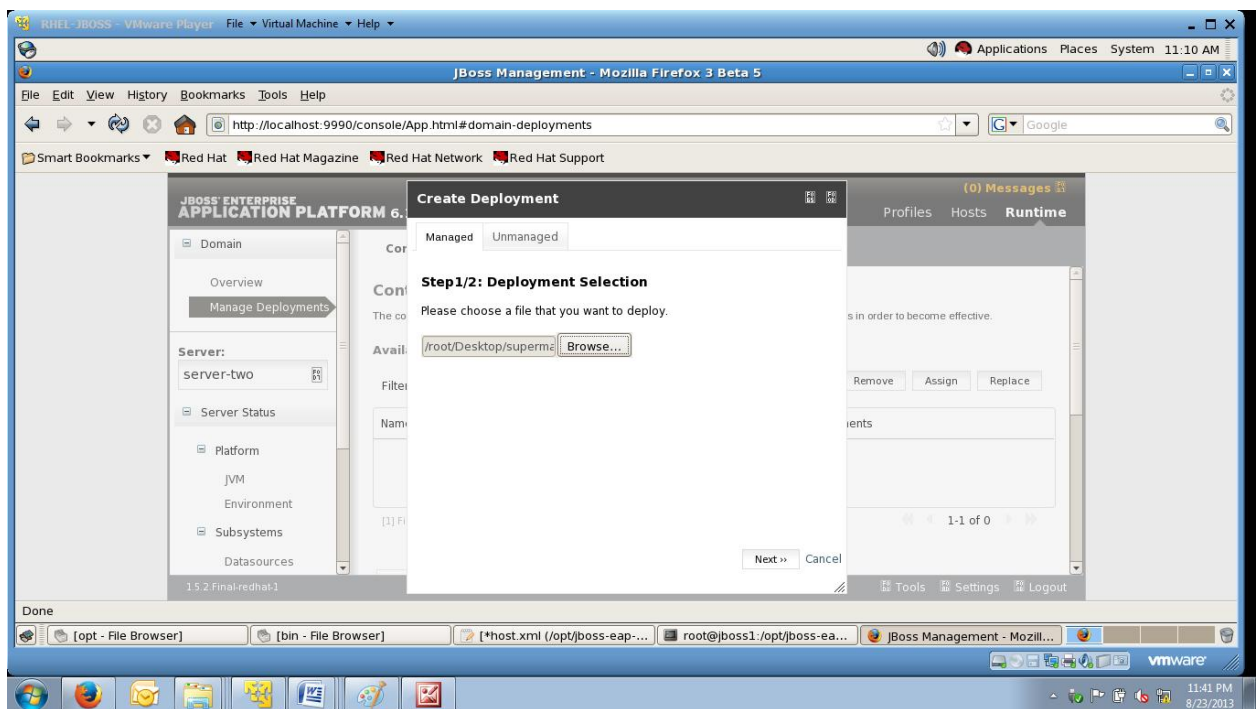

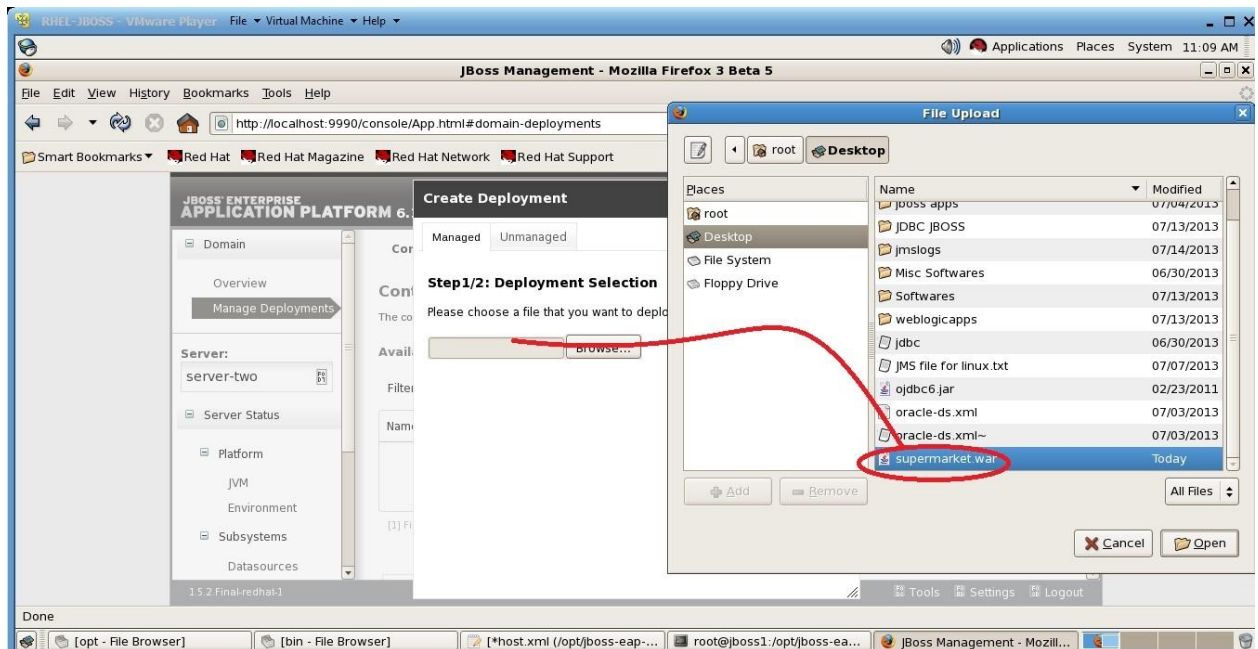

Now you can download one of our sample clustered application by : and deploy it from admin console from the URL "<http://localhost:9990/console>"

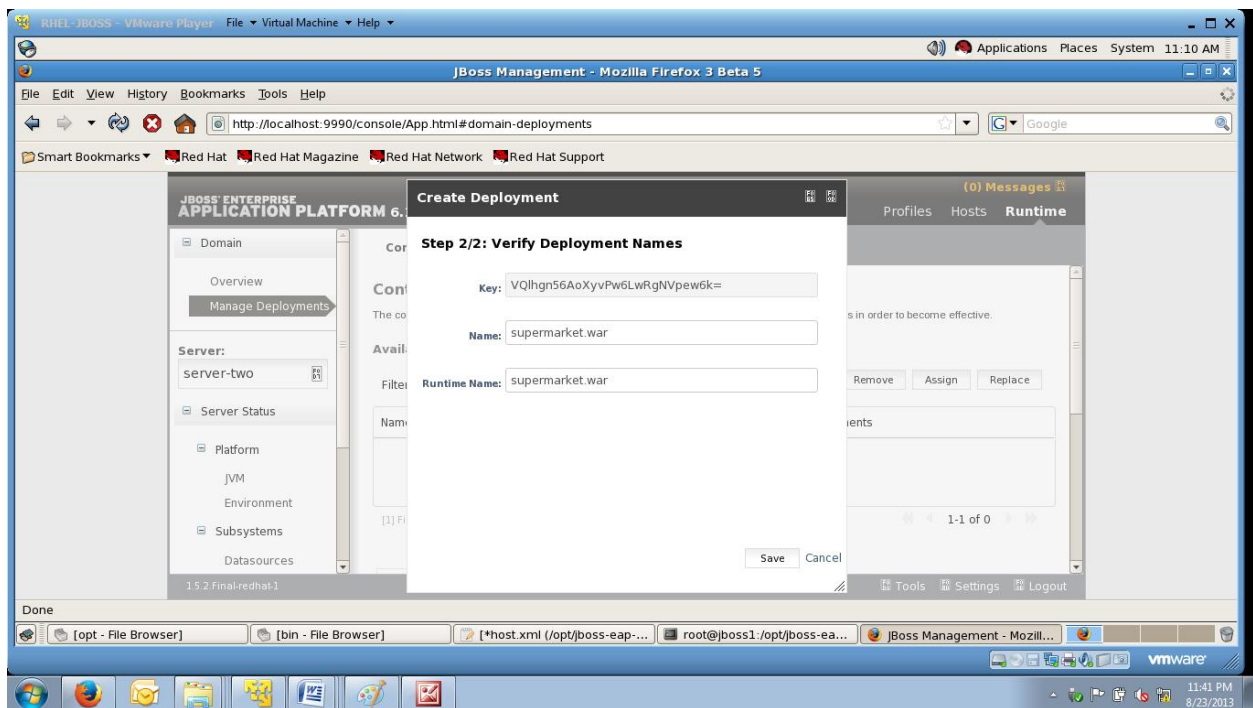

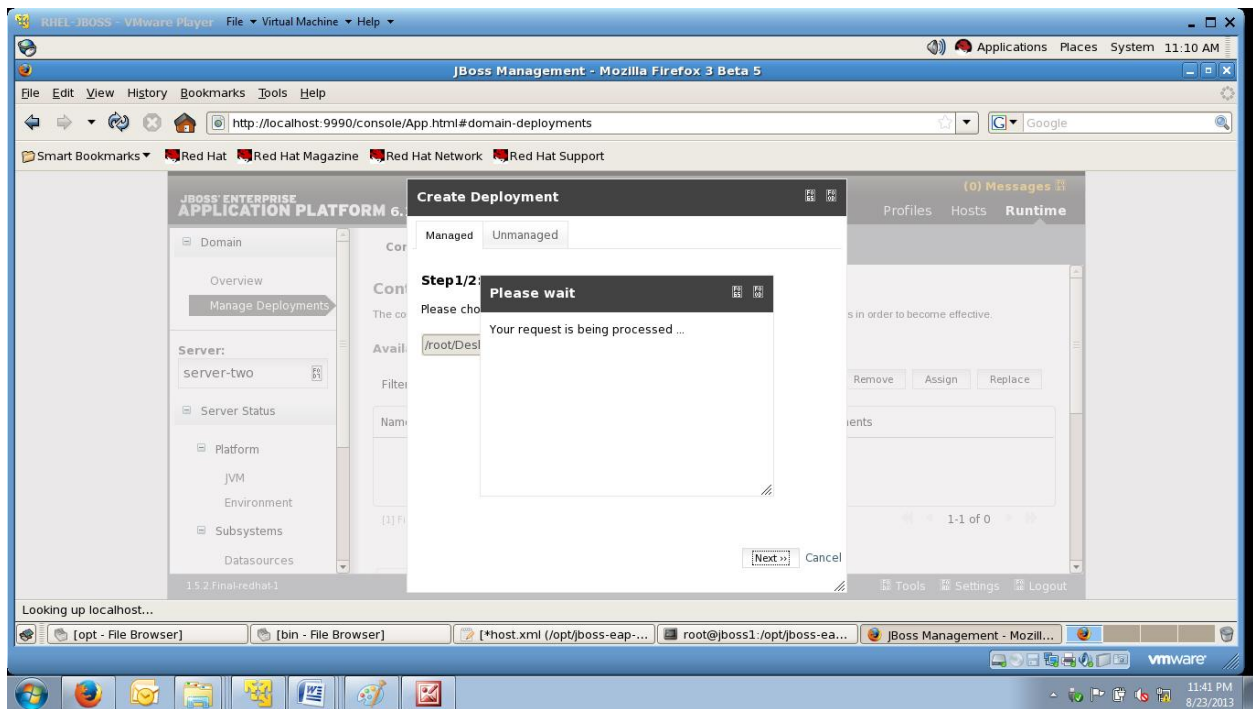

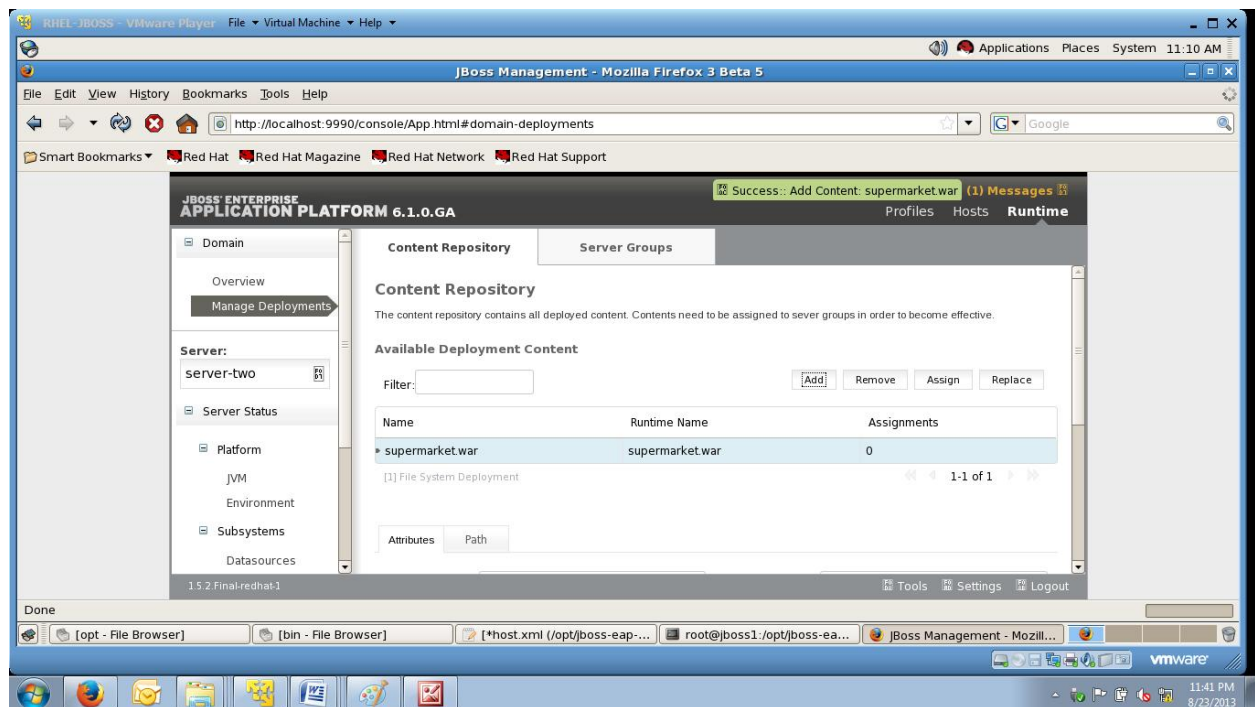

Deploy the application (Cluster deployment)

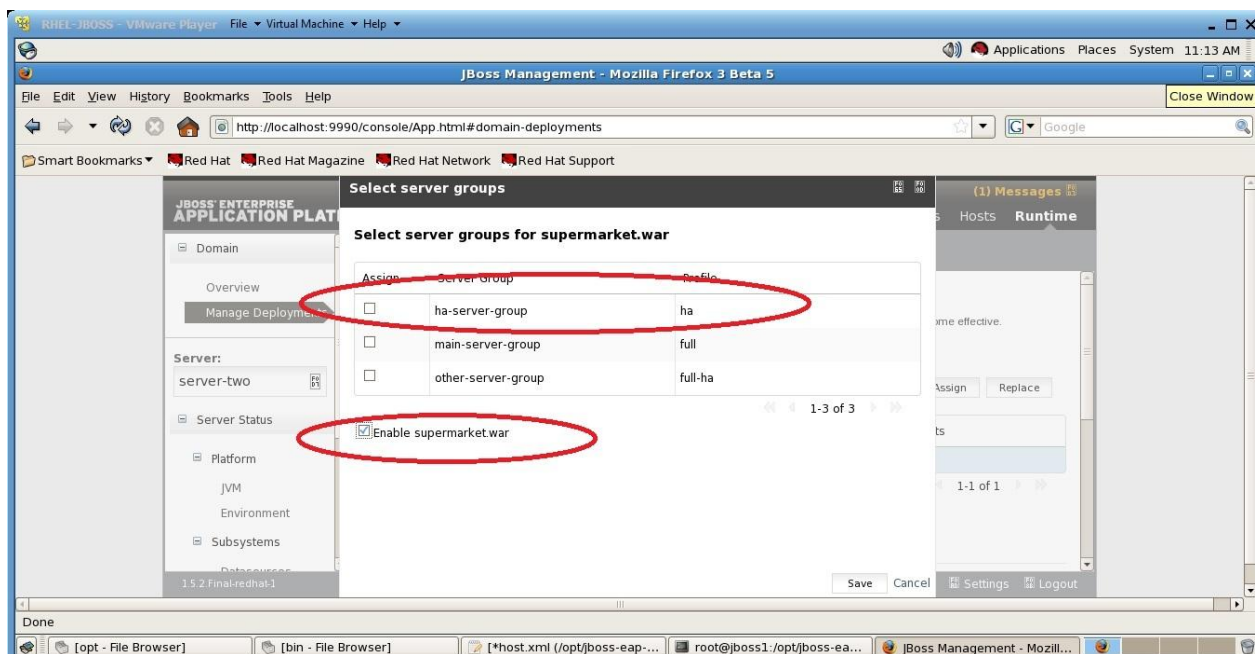

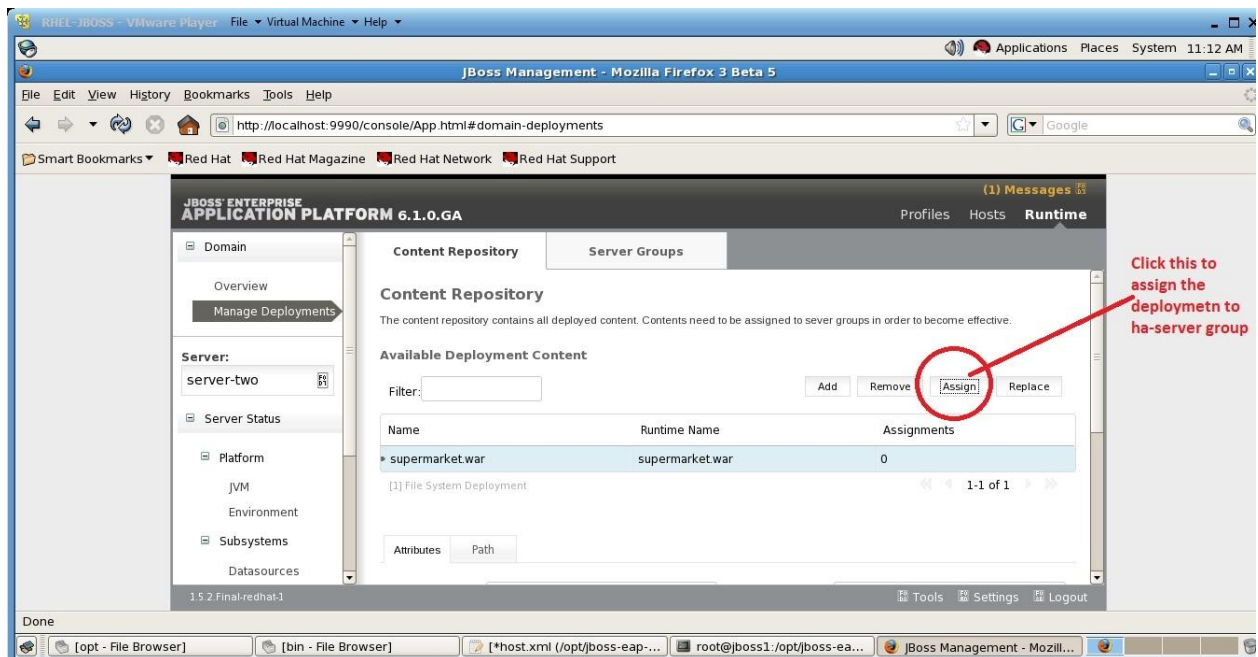

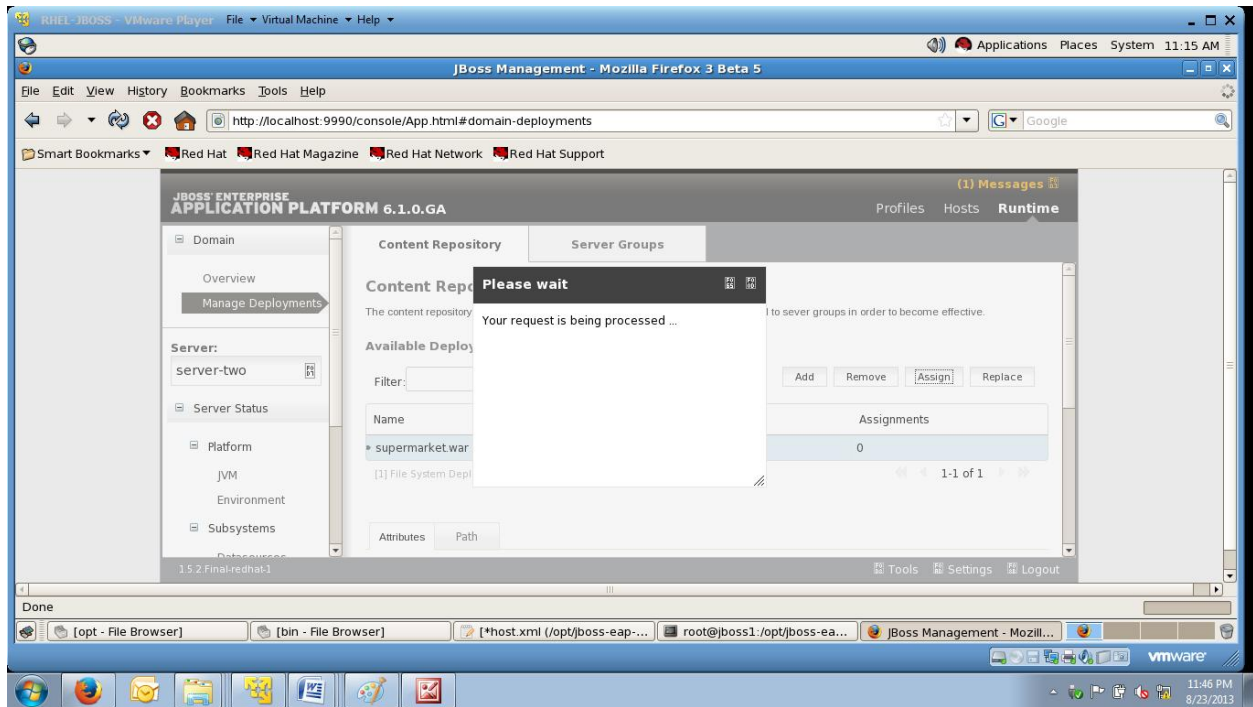

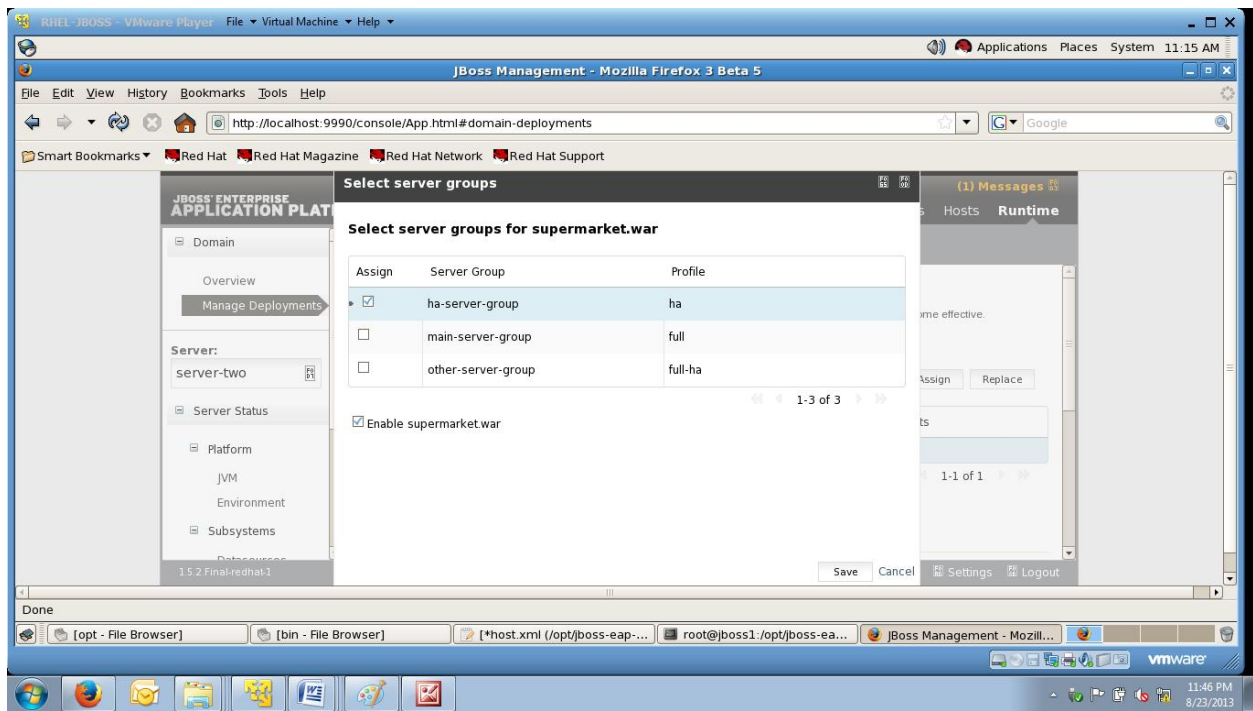

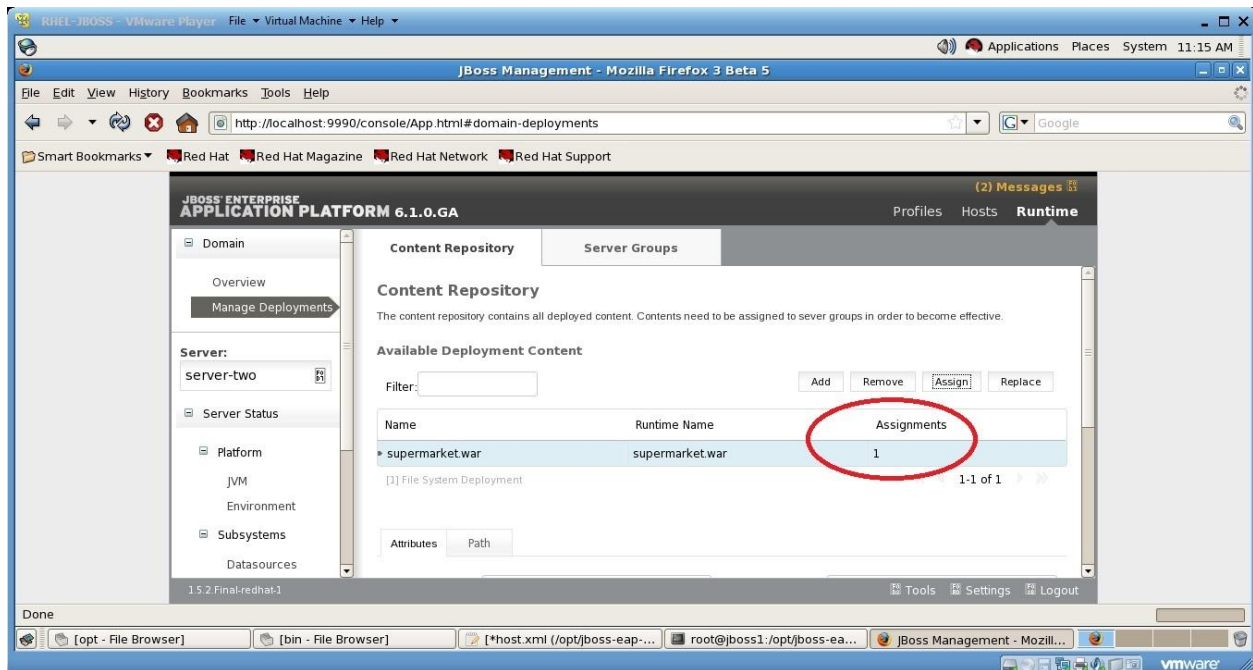

*****IMPORTANT****After picking the app,assign the server group to be deployed

*****IMPORTANT*****
